

Git Commands Cheat Sheet - Task 20

Student: Alejandro Mancheño | Course: 1st DAW

This is a quick reference guide with the terminal (CLI) commands I used to create, manage, and upload my Task Manager to GitHub.

1. Initialize and save changes

Command	What is it for?
<code>git init</code>	Creates a new, empty Git repository in the current folder.
<code>git status</code>	Shows the status of the project (new, modified, or unsaved files).
<code>git add .</code>	Adds and stages all modified files in the folder to be saved.
<code>git commit -m "message"</code>	Takes a "snapshot" of the staged changes and saves them to the history with a brief description.

2. Branch Management (Branching)

Command	What is it for?
<code>git checkout -b <name></code>	Creates a new branch (to test code without breaking the main one) and switches directly to it.
<code>git checkout <name></code>	Used to move from one existing branch to another (for example, <code>git checkout main</code>).
<code>git merge <name></code>	Joins or merges the changes made in the secondary branch with the branch we are currently on.

3. Connection and upload to GitHub (Remote)

Command	What is it for?
<code>git remote add origin <url></code>	Links my computer folder with an empty repository I created on the GitHub website.
<code>git branch -M main</code>	Renames the main branch of the project to "main" (the current GitHub standard).

<code>git push -u origin main</code>	Uploads the entire history, commits, and code from my computer to the GitHub cloud for the first time. For subsequent times, simply using <code>git push</code> is enough.
